

what do i do with this?

Based on the screenshot `image_a96e26.png` from Google Search Console, your URL `[https://fengshuiandbeyond.com/horoscope]` (`https://fengshuiandbeyond.com/horoscope`) is currently in the "Crawled - currently not indexed" state.

The good news is that there are no technical blockers: Googlebot successfully fetched the page, crawling is allowed, and indexing is permitted. It simply means Google has looked at the page but hasn't added it to the search results yet.

Here is exactly what you should do to address this:

1. Hit "Request Indexing"

Since the last crawl was very recent (June 30, 2026) and the page is technically sound, the first immediate step is to click the **REQUEST INDEXING** button located in the top right of that main notice block. This nudges Google to prioritize re-evaluating the page.

2. Fix the Sitemap Issue

Under the **Discovery** section, it says: `Sitemaps: No referring sitemaps detected`.

- **Action:** Ensure this specific URL is included in your XML sitemap.
- If it is already there, make sure you have submitted that sitemap under the **Sitemaps** tab on the left-hand menu of Search Console. Providing a sitemap path gives Google a clear roadmap to discover and contextualize the page.

3. Build Internal Links

The discovery section shows it found the page via the homepage

(`[https://fengshuiandbeyond.com/]` (`https://fengshuiandbeyond.com/`)).

- **Action:** To signal to Google that this page is important, add a few more internal links to it from other relevant articles or pages on your site. If a page only has one internal link, Google sometimes deprioritizes indexing it.

4. Review Content Value (The "Quality" Check)

Google frequently leaves pages in "Crawled - currently not indexed" if it perceives the content as thin, highly repetitive, or lacking enough unique value compared to what's already on the web.

- **Action:** Take a quick look at the `/horoscope` page. Ensure it has substantial, original textual content and isn't just a blank placeholder, a template, or a wall of short, automated text. Adding a bit more unique commentary or depth can push it over the line.

Once you request indexing and ensure it's in your sitemap, it usually takes anywhere from a few days to a couple of weeks for Google to update its status.

Is this a brand new page you recently launched, or has it been sitting online for a while?

how can i make the "waiting" faster?

Since the live test in `image_a97602.png` proves that the page is completely green and ready to go, waiting for Google's standard queue can be frustrating.

If you want to force Google's hand and speed up the process, use these actionable "fast-track" tactics:

1. Click "Request Indexing" Right Now on the Live Test

In `image_a97602.png`, you are currently looking at the **Live Test** tab. Make sure you actually click that **REQUEST INDEXING** link on this screen if you haven't already. Submitting it directly from a successful live test confirms to Google that the live version is valid.

2. The "High-Traffic Internal Link" Piggyback

Googlebot crawls your site based on a "crawl budget." If it visits your homepage or an older, popular blog post every single day, leverage that traffic:

- Place a prominent text link to `/horoscope` right on your homepage or your most popular live page.

- Go to Search Console, inspect that *highly-trafficked page*, and hit **Request Indexing** on *it* instead.
- When Googlebot instantly stops by to re-crawl your top page, it will discover the new link and follow it straight to your horoscope page.

3. Trigger a Fast External Crawl (Social Shares)

Googlebot monitors high-activity platforms around the clock to capture real-time data.

- Share the exact URL on **X (Twitter)**, **LinkedIn**, or a relevant public **Reddit** community.
- Because Google indexes these platforms rapidly, its bots often follow external links back to your site within hours.

4. Direct API Submission (The Technical Route)

If you have a lot of pages shifting around or frequently want instant results, look into the **Google Indexing API**.

- While Google officially states this API is for "Job Postings and Live Streams," the SEO and developer communities widely use it to get standard pages indexed within hours rather than days.
- There are quick Node.js scripts or open-source packages (like `google-indexing-api` on npm) that allow you to bypass the Search Console UI entirely and send an instant publish notification directly to Google's indexing pipeline.

For a single page, trying **Step 2** and **Step 3** usually cuts the wait time down from weeks to less than 24–48 hours.

sitemap

tell me more about the technical route. my website came live since september 2025. i had issues before as there were rerouting issues but until now i cant get my pages to be indexed. possible to submit all these pages in the attachment via direct api submission?

Your sitemap is perfectly structured, and the target URL

`https://fengshuiandbeyond.com/horoscope` is explicitly present in it.

Given that your site has been live since September 2025 and you previously had routing issues, it is highly likely that Googlebot slowed down its crawl rate due to encountering broken paths or redirects in the past. When Google hits early routing errors, it lowers your site's **Crawl Budget** (how often and how deeply it indexes your pages).

The **Google Indexing API** is the ultimate tool to break through this backlog. It forces Googlebot to immediately visit your pages, completely bypassing the standard slow queue. And yes, you can absolutely batch-submit all 65+ pages found in your sitemap attachment using it.

Here is the blueprint for how the technical route works and how to set it up:

How the Google Indexing API Works

Unlike Google Search Console, which merely "suggests" that Google look at a page, the Indexing API directly informs Google's real-time crawling queue that a URL has been updated or created.

Typically, you can send up to **200 requests per day** for free, which is more than enough to handle your entire sitemap in one go.

Step-by-Step Implementation

Because you have your sitemap ready, you can fully automate this process using Node.js.

Step 1: Create a Google Cloud Project & Service Account

1. Go to the [Google Cloud Console](#).
2. Create a new project (e.g., `FengShui-Indexing`).
3. Search for the **Web Search Indexing API** and click **Enable**.
4. Go to **IAM & Admin > Service Accounts** and click **Create Service Account**.
5. Give it a name, skip the optional roles, and click **Done**.
6. Click on your newly created service account email, navigate to the **Keys** tab, click **Add Key > Create New Key**, and choose **JSON**.
7. Save this file securely as `service-account.json` . Inside, you will see a unique email address ending in `.gserviceaccount.com` .

Step 2: Grant Permissions in Google Search Console

Google needs to know that your automated script actually owns the website.

1. Open your **Google Search Console**.
2. Go to **Settings > Users and permissions**.
3. Click **Add User**.

4. Paste the `.gserviceaccount.com` email address you copied from your JSON file.
5. **Crucial:** Set the Permission level to **Owner**. (The API will fail with a `403 Permission Denied` error if it is only set to 'Full' or 'Restricted').

Step 3: Run the Batch Node.js Script

You can write a simple Node.js script that parses your `sitemap.xml` file and loops through each URL to notify Google.

1. Initialize a project folder and install the official Google authentication library:

Bash

```
npm init -y
npm install googleapis axios
```

2. Create an `index.js` script to process your batch updates. It authenticates using your key and sends a `URL_UPDATED` notification for each link:

JavaScript

```
const { google } = require('googleapis');
const fs = require('fs');

// Load your downloaded service account key
const key = require('./service-account.json');

const jwtClient = new google.auth.JWT(
  key.client_email,
  null,
  key.private_key,
  ['https://www.googleapis.com/auth/indexing'],
  null
);

// Array of your sitemap URLs to force-index
const urlsToSubmit = [
  "https://fengshuiandbeyond.com/",
  "https://fengshuiandbeyond.com/horoscope",
  "https://fengshuiandbeyond.com/astrology",
  // ... Paste the rest of your sitemap links here
];

async function fastTrackIndexing() {
  await jwtClient.authorize();
```

```

console.log("Authenticated successfully with Google API.");

for (const url of urlsToSubmit) {
  try {
    const response = await google.indexing({ version: 'v3', auth: jwtClient }).urlN
      requestBody: {
        url: url,
        type: 'URL_UPDATED' // Forces Google to re-crawl and evaluate the page
      }
    });
    console.log(`🚀 Success: ${url} status sent. Response:`, response.statusText);
  } catch (error) {
    console.error(`❌ Failed for ${url}:`, error.message);
  }
  // Small delay to prevent hitting aggressive rate limits instantly
  await new Promise(resolve => setTimeout(resolve, 500));
}
}

fastTrackIndexing();

```

Alternative: The Low-Code Solution

If you use a headless CMS framework or don't want to maintain a custom script, there are pre-built desktop applications and extensions designed specifically for this:

- **Open-Source Tools:** Search Github for `google-indexing-api-desktop`. There are simple GUI tools where you just drag-and-drop your `service-account.json` file and paste your raw sitemap list into a text box.
- **WordPress (If applicable):** If your site backend runs on a system like WordPress, the *Instant Indexing by RankMath* plugin implements this exact API pipeline completely automatically whenever you hit publish.

What to Expect Next

Once you run the script, check your console output. If you see `200 OK` responses, Google's internal queue has received the requests.

Because your pages are already "clean" according to the live test you did earlier, you will usually see Googlebot hit your server logs within minutes, and the pages should begin trickling into the Google index over the next 24 to 48 hours.
